

## Overview of Carbonyl Compounds.

1. Kinds of Carbonyl Compounds.
  - a) Aldehydes and ketones. No leaving group attached to carbonyl C. Oxidation state +2.
  - b) Carboxylic acids and their derivatives: esters, amides, acyl chlorides, acyl anhydrides. One leaving group attached to carbonyl C. Oxidation state +3. Nitriles are honorary members of the carboxylic acid family, and have much the same reactivity.
  - c) Carbonates and their derivatives: urethanes (carbamates), ureas. Two leaving groups attached to carbonyl C. Oxidation state +4.
  - d)  $\text{CO}_2$ .
2. Reactivity of carbonyl compounds.
  - a) Basic at O. O reacts with  $\text{H}^+$  or other Lewis acids such as  $\text{BF}_3$ , etc. Not much else.
  - b) Electrophilic at carbonyl C. Under basic conditions, reacts as is. Under acidic conditions, O is protonated to give a compound even more electrophilic at C.
  - c) Acidic at  $\alpha$ -C. Acidic because of electrophilic nature of carbonyl C. Under basic conditions, bases deprotonate immediately to give enolate. Under acidic conditions, protonated on O first, then weak base deprotonates at C to give enol. Both enolate and enol are nucleophilic at C (and O).

## Chapter 20. Addition of Hard Nucleophiles to Carbonyl Compounds.

1. Nucleophilic addition to aldehydes and ketones under basic conditions.
  - a) Aldehydes and ketones are *electrophilic* at the carbonyl C.  $\overset{+}{\text{C}}-\overset{-}{\text{O}}$  resonance structure.
  - b) Nucleophiles (usually anionic, except for amines) add to neutral carbonyl compounds. After the addition, the former carbonyl O is protonated to give the product.
    - i) Lone pair nucleophiles.  $\text{HO}^-$ ,  $\text{RO}^-$ ,  $\text{RC}\equiv\text{C}^-$ ,  $-\text{C}\equiv\text{N}$ ,  $\text{H}_3\text{N}$ ,  $\text{RNH}_2$ .
    - ii) Sigma bond nucleophiles.  $\text{NaBH}_4$  and  $\text{LiAlH}_4$  ( $\text{H}^-$  sources), Grignard reagents such as  $\text{EtMgBr}$  or  $\text{PhMgBr}$  ( $\text{R}^-$  sources), organolithium reagents such as  $\text{CH}_3\text{Li}$ .
2. Nucleophilic addition to carboxylic acid derivatives under basic conditions.
  - (a) Carboxylic acids and their analogs are electrophilic at the carbonyl C, just like aldehydes and ketones.
  - (b) Nucleophiles add to carbonyl C under basic conditions (except for carboxylic acids under basic conditions) to give a *tetrahedral intermediate*.
  - (c) After nucleophile adds, though, loss of a leaving group can occur to *re-form the carbonyl!* This is how carboxylic acid derivatives differ from ketones and aldehydes. Overall mechanism is called *addition-elimination*.
3. Reactions of carbonyls with reducing agents.
  - a) Aldehyde +  $\text{NaBH}_4$  or  $\text{LiAlH}_4 \rightarrow 1^\circ$  alcohol. Work-up necessary.
  - b) Ketone +  $\text{NaBH}_4$  or  $\text{LiAlH}_4 \rightarrow 2^\circ$  alcohol. Work-up necessary.
  - c) Acids +  $\text{LiAlH}_4 \rightarrow 1^\circ$  alcohols, but hard to do; better to make ester or acyl chloride first.

- d) Acyl chloride +  $\text{LiAlH}_4$  or  $\text{NaBH}_4$  or DIBAL  $\rightarrow$   $1^\circ$  alcohols.
- e) Esters
- +  $\text{LiAlH}_4 \rightarrow$   $1^\circ$  alcohols. Addition–elimination–addition.
  - + DIBAL  $\rightarrow$  aldehydes. Addition–elimination.
  - $\text{NaBH}_4$  reacts only slowly with esters, so ketones can be reduced with  $\text{NaBH}_4$  in presence of esters, but not vice versa
- f) Nitriles
- + DIBAL  $\rightarrow$  aldehyde. Addition.
  - +  $\text{LiAlH}_4 \rightarrow$   $1^\circ$  amines. Addition, then addition again.
  - $\text{NaBH}_4$  does not react with nitriles
- g) Amides
- +  $\text{LiAlH}_4$  or DIBAL  $\rightarrow$   $1^\circ$  amines. Addition–elimination–addition.
  - $\text{NaBH}_4$  does not react with amides
4. Reactions of carbonyls with hard nucleophiles.
- Kinds of hard nucleophiles.
    - Grignard and organolithium reagents made from halides.
    - Acetylides made by deprotonating alkynes.
  - Aldehyde +  $\text{RMgBr} \rightarrow$   $2^\circ$  alcohol; ketone +  $\text{RMgBr} \rightarrow$   $3^\circ$  alcohol. Work-up necessary.  
**Another way to make C–C bond!**
  - Esters +  $\text{RMgBr} \rightarrow$   $3^\circ$  alcohols. Addition–elimination–addition. **Makes a C–C bond!**
  - $\text{CO}_2$  +  $\text{RMgBr} \rightarrow$  carboxylic acid. **Makes a C–C bond!**
  - Nitriles +  $\text{RMgBr} \rightarrow$  ketone. **Makes a C–C bond!**
  - Amides +  $\text{RMgBr}$  not a useful reaction
  - Acids +  $\text{RMgBr}$  not a useful reaction
5. Oxidation of aldehydes and ketones.
- $1^\circ$  and  $2^\circ$  alcohols to aldehydes and ketones with PCC.  $\text{RCH}_2\text{OH} + \text{PCC} \rightarrow \text{RCHO}$ ;  $\text{R}_2\text{CHOH} + \text{PCC} \rightarrow \text{R}_2\text{C=O}$ . Cr acts as electrophile toward OH, then acts as leaving group in elimination.
  - $1^\circ$  alcohols and aldehydes to acids with Jones' reagent.  $\text{RCHO} + \text{CrO}_3/\text{H}_2\text{SO}_4 \rightarrow \text{RCO}_2\text{H}$ . Proceeds through hydrate.
6. Retrosynthetic analysis of alcohols, ketones, carboxylic acids.
